Clock Driver Quad D-Type Flip-Flop With Matched Propagation Delays

The MC74F803 is a high-speed, low-power, quad D-type flip-flop featuring separate D-type inputs, and inverting outputs with closely matched propagation delays. With a buffered clock (CP) input that is common to all flip-flops, the F803 is useful in high-frequency systems as a clock driver, providing multiple outputs that are synchronous. Because of the matched propagation delays, the duty cycles of the output waveforms in a clock driver application are symmetrical within 1.0 to 1.5 nanoseconds.

CLOCK DRIVER QUAD D-TYPE FLIP-FLOP WITH MATCHED PROPAGATION DELAYS

FUNCTIONAL DESCRIPTION

The F803 consists of four positive edge-triggered flip-flops with individual D-type inputs and inverting outputs. The buffered clock is common to all flip-flops and the following specifications allow for outputs switching simultaneously. The four flip-flops store the state of their individual D inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. The maximum frequency of the clock input is 70 megahertz, and the LOW-to-HIGH and HIGH-to-LOW propagation delays of the $\overline{\text{O}}_1$ output vary by, at most, 1 nanosecond. Therefore, the device is ideal for use as a divide-

by-two driver for high-frequency clock signals that require symmetrical duty cycles. The difference between the LOW-to-HIGH and HIGH-to-LOW propagation delays for the \overline{O}_0 , \overline{O}_2 , and \overline{O}_3 outputs vary by at most 1.5 nanoseconds. These outputs are very useful as clock drivers for circuits with less stringent requirements. In addition, the output-to-output skew is a maximum of 1.5 nanoseconds. Finally, the IOH specification at 2.5 volts is guaranteed to be at least – 20 milliamps. If their inputs are identical, multiple outputs can be tied together and the IOH is commensurately increased.

^{1.} The test conditions used are all four outputs switching simultaneously. The AC characteristics described above (except for O₁) are also guaranteed when two outputs are tied together.

^{1.} For conditions such as MIN or MAX, use the appropriate value specified under guaranteed operating ranges.

^{2.} Not more than one output should be shorted at a time, nor for more than 1 second.

^{2.} Where to On and to Om are the actual propagation delays (any combination of high or low) for two separate outputs from a given high transition of CP.

^{3.} For a given set of conditions (i.e., capacitive load, temperature, V_{CC}, and number of outputs switching simultaneously) the variation from device to device is guaranteed to be less than or equal to the maximum.

AC OPERATING REQUIREMENTS ($T_A = 0$ to $70^{\circ}C$, $V_{CC} = 5.0 \text{ V} \pm 10\%$)

The combination of the setup time (t_s) requirement and maximum propagation delay (t_p) are guaranteed to be within this limit for all conditions.

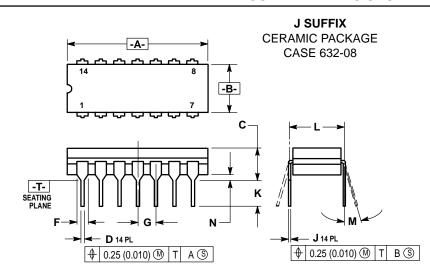

APPLICATION NOTE

The closely matched outputs of the MC74F803 provide an ideal interface for the clock input of Motorola's high-frequency microprocessors.
